

Real World Algorithms: A Beginners Guide

Errata to the Third Printing

Last updated 06 April 2020

This document lists the changes that should be made to *Real World Algorithms* to correct mistakes that made their way to printing, to improve infelicities that the author spotted too late, or update the material with something that the author did not know at the time of writing the book.

There are three different kinds of changes noted here. In all of them the date that they became known to the author is given at the first line of each item. The name of the person who suggested the change is also given at the end of each change.

► **Page 1, line 1** _____ 1 Jan 1

These are technical or typographical errors.

Page 1, line 1 _____ 1 Jan 1

These are changes that improve the book, even if they do not correct an error. They include small rewordings, or material that became known to the author after the book was published.

Page 1, line 1 _____ 1 Jan 1

These are minor fixes that although they do not make a big difference they do hurt the author. Some of them might strain the reader's eye to see where the improvement is exactly.

Therefore, in the worst case, which is if the quotes are in ascending order, line 7 will execute the following number of times:

$$1 + 2 + \cdots + n = \frac{n(n+1)}{2}$$

If the equation is not clear, then you can easily see that this is indeed so if you add the numbers $1, 2, \dots, n$ twice:

$$\begin{array}{ccccccc} 1 & + & 2 & + & \cdots & + & n \\ + & n & + & n-1 & + & \cdots & + & 1 \\ \hline n+1 & + & n+1 & + & \cdots & + & n+1 & = & n(n+1) \end{array}$$

Because line 6 is the step of the algorithm that will execute most times, $n(n+1)/2$ is the worst case running time of the algorithm.

↙↘

Therefore, in the worst case, which is if the quotes are in ascending order, lines 6–7 will execute the following number of times (recall that we start from day zero):

$$0 + 1 + 2 + \cdots + (n-1) = \frac{n(n-1)}{2}$$

If the equation is not clear, then you can easily see that this is indeed so if you start with the sum of $1, 2, \dots, n$ twice:

$$\left. \begin{array}{ccccccc} 1 & + & 2 & + & \cdots & + & n \\ + & n & + & n-1 & + & \cdots & + & 1 \\ \hline n+1 & + & n+1 & + & \cdots & + & n+1 \end{array} \right\} \begin{array}{l} \nearrow 1 + 2 + \cdots + n = \frac{n(n+1)}{2} \\ \searrow 1 + 2 + \cdots + (n-1) = \frac{n(n+1)}{2} - n = \frac{n(n-1)}{2} \end{array}$$

Because lines 6–7 are the steps of the algorithm that will execute most times, $n(n-1)/2$ is the worst case running time of the algorithm.
